Purpose: Enhanced external counterpulsation (EECP) is popular in China for the treatment of coronary heart diseases, but it may be an effective treatment for other populations. This study aimed to explore the effect of EECP on exercise endurance of healthy people and chronic obstructive pulmonary disease (COPD) patients and provide intervention measures to improve their physical condition.

Patients and methods: Patients were enrolled in this pilot randomized controlled trial at Jiangbin Hospital, China, between March 1st and May 30th, 2018. They were randomly divided into the EECP and non-EECP groups. According to their maximal oxygen uptake, the volunteers were also sub-grouped into the normal, low exercise endurance, and COPD subgroups. Differences in exercise endurance were evaluated between the EECP and non-EECP groups before and after treatment. Cardiopulmonary exercise testing included anaerobic threshold oxygen uptake (AT-VO₂Kg), maximum oxygen uptake (Max-VO₂Kg), anaerobic threshold pulse (AT-O₂puls), anaerobic threshold metabolic equivalent (AT-Mets), and maximum metabolic equivalent (Max-Mets).

Results: 72 volunteers were enrolled. The EECP and non-EECP groups were similar in terms of age, sex, body mass index, blood pressure, heart rate, breathing frequency, AT-VO₂ Kg, Max-VO₂Kg, AT-O₂puls, AT-Mets, and Max-Mets ($P > 0.05$) before treatment. EECP significantly improved AT-VO₂Kg, Max-VO₂Kg, AT-O₂puls, AT-Mets, and Max-Mets compared with the non-EECP group ($P < 0.05$). When analyzed according to sub-groups, the AT-VO₂Kg, Max-VO₂Kg, AT-O₂puls, AT-Mets, and Max-Mets of the normal, low exercise endurance, and COPD subgroups were all significantly increased after EECP ($P < 0.05$).

Conclusion: EECP significantly improved the exercise endurance of normal adults, low endurance adults, and COPD patients.

Registration number: ChiCTR1900021993.

Introduction

Sports ability is the ability to participate in sports and training, which is closely related to the comprehensive functions of the heart, brain, lung, skeletal muscle, and endocrine systems.¹ Sports ability can objectively reflect the overall function of the body and is a powerful predictor of death, even for healthy people with low exercise ability.² Therefore, exercise is of great significance to improve physical condition, enhance resistance of disease, and prolong life.³

Enhanced external counterpulsation (EECP) is an effective method for the treatment of coronary heart disease and is used widely in China.⁴ It is a safe and effective non-invasive mechanical auxiliary circulation method.⁵ The technique mainly consists of three sets of airbags wrapped around the calf, thigh, and buttocks. EECP consists of applying intermittent positive pressure to the lower body, with this pressure being synchronized with the subject's cardiac cycle, i.e., being sequentially applied distally to proximally at early diastole, and released at the end of diastole. The airbag is pumped up from the lower legs, thighs, and buttocks, which triggers an electrocardiogram (ECG) R wave, by squeezing the arteriovenous system of the lower half of the body.⁶ By pressing the lower body arterial system, the arterial blood flows to the upper body of the body, which can improve the blood perfusion of vital organs such as the heart and brain. Moreover, by pressing the lower body vein system, the venous reflux of the right heart is increased, and cardiac output is increased through the Frank-Starling mechanism.^{7,8} Recent studies showed that EECP could significantly improve myocardial blood supply,^{9,10} and it may have a role in improving exercise endurance.¹¹ This mechanism is different from that of BFRE, which induces hypoxia in the extremities by restricting the returned blood volume, increasing the tolerability of muscles to hypoxia.¹² EECP is documented in the Expert Consensus and Guidelines for Cardiac Rehabilitation in China as an effective method for the treatment of chronic heart failure, and coronary heart diseases.¹³ EECP has the EC and FDA approvals.

Most studies of EECP involve patients with cardiovascular disease and have only undertaken a superficial investigation into exercise endurance. Other populations may benefit from receiving EECP, including healthy adults and those with chronic obstructive pulmonary disease (COPD). COPD is a common chronic respiratory disorder with airflow limitation and increased inflammatory response in the airways, and it is currently a massive global burden.¹⁴ Recurrent COPD attacks can lead to increased pulmonary arterial pressure, resulting in increased right atrial load and progression to pulmonary heart disease.¹⁵ Although the clinical symptoms of patients are relieved after an acute episode, pulmonary function continues to deteriorate, exercise endurance is significantly reduced, and the patient's quality of life is seriously affected.¹⁶

We hypothesized that EECP might be able to improve the exercise endurance of different groups of adults and might improve the physical condition and the prognosis of

patients with COPD. Therefore, the aim of this study was to evaluate whether EECP could improve exercise endurance of healthy adults and those with COPD.

Materials and Methods

Subjects

The volunteers were enrolled at the Cardiopulmonary Rehabilitation Center of Jiangbin Hospital (China) from March 1st to May 30th, 2018. Inclusion criteria: 1) aged ≥ 18 years old; 2) healthy people and patients diagnosed with COPD but no acute attack according to the Global Strategy for the Diagnosis, Management, and Prevention of Chronic Obstructive Lung Disease 2017 guidelines;¹⁷ and 3) no operation and injury history. The subjects were excluded from the study if they had heart disease, cerebral disease, pneumonia, liver and kidney disease, neurological diseases, or other infections. As per the device's indications, individuals with blood pressure $\geq 160/90$ mmHg were excluded.

This preliminary randomized controlled trial was approved by the institutional review board of Jiangbin Hospital. Written informed consent was obtained from all the patients. The study was registered (ChiCTR1900021993).

Randomization, Subgroup, and Intervention

The subjects were randomized (1:1) into the EECP group and non-EECP group using a random number table. According to the maximal oxygen uptake ($VO_2\max$) of cardiopulmonary exercise testing (CPET), the subjects were also divided into subgroups as follows: normal subgroup ($VO_2\max \geq 84\%$ prediction of $VO_2\max$), low exercise endurance subgroup ($VO_2\max < 84\%$ prediction of $VO_2\max$), and COPD subgroup.

The EECP equipment (P-ECP/TI, Chongqing PSK-health Sci-Tech Development Co.,Ltd, China) consisted of an ECG monitor and air compressor that could cover two legs and the hip. Before the treatment began, the air compressor cuffs were wrapped around the subject's limbs. The primary cuff was empty without pressure. When EECP therapy began, a sequence of synchronized pressure was given according to the cardiac cycle. In early ventricular diastole, the compressor increased the pressure of the cuffs in sequence from the lower legs to the upper legs and the hips. This regular succession improved the arterial blood pressure and blood flow during the diastolic period. At the end of the diastole,

the air in the cuff was released promptly, which reduced vascular impedance. According to the instruction manual, the maximal cuff pressure was set as 0.03 mPa. An experienced and trained physician operated the equipment in this study. All subjects in the EECP group underwent EECP therapy for 1 hr/day, 5 days/week, for 3 weeks, and the non-EECP group did not.

Assessment

The German Cortex CPET system (CPX International, Germany) was used to test the anaerobic threshold of the subjects during exercise. The measurements included anaerobic threshold oxygen uptake (AT-VO₂Kg), maximum oxygen uptake (Max-VO₂Kg), anaerobic threshold pulse (AT-O₂puls), anaerobic threshold training load (AT-Load), anaerobic threshold metabolic equivalent (AT-Mets), and maximum metabolic equivalent (Max-Mets).

Symptom-limited cardiopulmonary exercise testing (CPET) on a bike was performed at baseline (the day before EECP treatment) and on the day after EECP treatment finished. Testing was terminated if there was the onset of angina pain, dizziness, dyspnea, or arrhythmia on 12-lead electric-cardiogram (ECG), or reluctance of the subject to continue the exercise testing.

Safety was assessed through adverse event monitoring such as skin damage, chest tightness, muscular pain, embolism, etc.

Statistical Analysis

The full analysis set (all randomized participants who received at least one treatment and had at least one post-baseline efficacy assessment) and safety set (all randomized participants who received at least one treatment and had at least one post-baseline safety assessment) were used for analysis. All statistical analyses were performed using SPSS Statistics 17 for Windows (IBM, Armonk, NY, USA). Continuous variables are expressed as means ± standard deviations (SD). Comparisons between the EECP and non-EECP groups were made with the independent *t*-test. The paired *t*-test was used for comparison before and after EECP treatment. Categorical variables are expressed as numbers (percentages). Comparisons were made using the chi-square or Fisher's exact test. The analyzed effects were the differences before and after the treatment and the corresponding *P*-value and 95% CIs. *P*<0.05 was stipulated for statistical significance.

Results

Eighty-two volunteers were eligible. Six volunteers withdrew their consent. One was lost to follow-up. Three discontinued intervention because of acute exacerbations of COPD (n=2) and burn injury (n=1). Finally, there were 39 males and 33 females, aged 27–82 years. They were divided into the EECP group (n=37, aged 57.30±21.16 years) and the non-EECP group (n=35, aged 54.23±23.37 years) (Figure S1). For the EECP group, there were 11, 13, and 13 volunteers in the normal, low exercise endurance, and COPD subgroups, respectively. For the non-EECP group, there were 15, 10, and 10 volunteers in the normal, low exercise endurance, and COPD subgroups, respectively.

The EECP and non-EECP groups were similar in terms of age, gender, body mass index (BMI), blood pressure, heart rate, breathing frequency, AT-VO₂Kg, Max-VO₂Kg, AT-O₂puls, AT-Mets, and Max-Mets (*P*>0.05) before treatment, as shown in Table S1.

Comparison of Exercise Endurance

There were no statistically significant differences between the two groups before treatment in anaerobic threshold heart rate (AT-HR), anaerobic threshold inter-beat interval (AT-RR), anaerobic threshold systolic blood pressure (AT-SBP), anaerobic threshold diastolic blood pressure (AT-DBP), maximum systolic blood pressure (Max-SBP), maximum diastolic blood pressure (Max-DBP), AT-VO₂Kg, Max-VO₂Kg, AT-O₂puls, and Max-Mets (all *P*>0.05); the same was found after EECP treatment (*P*>0.05). When the two groups were compared after treatment, there were significant differences of AT-VO₂Kg, Max-VO₂Kg, AT-O₂puls, AT-Load, AT-Mets, and Max-Mets between the EECP and non-EECP groups (all *P*<0.05) (Table S2).

Subgroup Analysis

Comparison of Exercise Endurance in the Normal Population Subgroup

There were no statistically significant differences between the two groups (EECP group, n=11; non-EECP group, n=15) before treatment in terms of AT-HR, AT-RR, AT-SBP, AT-DBP, Max-SBP, Max-DBP, AT-VO₂Kg, Max-VO₂Kg, AT-O₂puls, AT-O₂puls, and Max-Mets (all P>0.05); the same was found after EECP treatment (all P>0.05). When the two groups were compared before and after treatment, AT-VO₂Kg, Max-VO₂Kg, AT-O₂puls, AT-Load, AT-Mets, and Max-Mets were all more significantly improved in the EECP group than in the non-EECP group (all P<0.05) (Tables 1 and 2).

Comparison of Exercise Endurance in the Low Exercise Endurance Subgroup

There were no statistically significant differences between the two groups before treatment in AT-HR, AT-RR, AT-SBP, AT-DBP, Max-SBP, Max-DBP, AT-VO₂Kg, Max-VO₂Kg, AT-O₂puls, and Max-Mets (all P>0.05); the same was found after EECP treatment (all P>0.05). When the two groups were compared before and after treatment, AT-VO₂Kg, Max-VO₂Kg, AT-O₂puls, AT-Load, AT-Mets, and Max-Mets were all more significantly improved in the EECP group compared with the non-EECP group (all P<0.05) (Tables 3 and 4).

Comparison of Exercise Endurance in the COPD Subgroup

There were no statistically significant differences between the two groups before treatment in AT-HR, AT-RR, AT-SBP, AT-DBP, Max-SBP, Max-DBP, AT-VO₂Kg, Max-

Table 3 Comparison of General Data Between the Groups in the Low Exercise Endurance Subgroup

VO₂Kg, AT-O₂puls, and Max-Mets (all P>0.05); the same was found after EECP treatment (all P>0.05). When the two groups were compared before and after treatment, AT-VO₂Kg, Max-VO₂Kg, AT-O₂puls, AT-Load, AT-Mets, and Max-Mets were all more significantly improved in the EECP group compared with the non-EECP group (all P<0.05) (Tables 5 and 6).

Safety

No subject had any adverse event in this trial.

Discussion

The aim of this study was to investigate whether EECP was able to improve the exercise endurance of healthy adults, those with low exercise endurance, and patients with COPD. The results showed that EECP significantly improved AT-VO₂Kg, Max-VO₂Kg, AT-O₂puls, AT-Mets,

and Max-Mets in the overall population of this study. When analyzed according to subgroups, the AT-VO₂Kg, Max-VO₂Kg, AT-O₂puls, AT-Mets, and Max-Mets of the normal, low exercise endurance, and COPD subgroups were all significantly increased after EECP. Therefore, these results suggest that EECP is likely to improve exercise endurance in different populations of adults.

Study suggests that athletic ability is closely related to the mortality risk,¹ but previous studies of EECP were focused on patients with coronary heart diseases,^{18–20} and there are relatively few studies on exercise endurance of other populations including normal and healthy people. Peak-VO₂Kg is the gold standard for the evaluation of cardiopulmonary fitness, Max-VO₂Kg is used to evaluate endurance, and AT-VO₂Kg is used in the evaluation of aerobic exercise

capacity.²¹ The present study showed that exercise endurance evaluation indexes such as AT-VO₂Kg, Max-VO₂Kg, AT-O₂puls, AT-Load, AT-Mets, and Max-Mets were improved after EECP therapy in the general population without cardiovascular diseases. This suggests that EECP can generally improve exercise endurance. This is contradicted by another study that was undertaken in 12 elite junior triathletes that looked at the role of EECP in recovery after a high-intensity interval training session (six bouts of 3-mins duration at maximal intensity interspersed with 3-min rest periods).²² In that study, EECP did not enhance short-term recovery, but exercise endurance was not a major endpoint, and the population was very different from the present study. Therefore, the studies are not directly comparable.

According to the differences in condition and exercise capacity of the subjects, we conducted a subgroup analysis of the normal, low exercise endurance, and COPD subgroups. The results showed that after EECP treatment, their exercise endurance was higher than those who were untreated. Furthermore, the increase of diastolic blood pressure in the process of exercise cardiopulmonary test after EECP treatment was lower than before treatment, and this is probably due to the effect of external counterpulsation in regulating blood pressure and heart rate.^{23,24} These changes may be related to the improvement of cardiovascular fitness and cardiac function with EECP therapy. EECP therapy can improve cardiac function and oxygen uptake;²⁵ moreover, cardiac function is significantly correlated with exercise capacity. For the normal and low endurance populations, EECP can increase the blood flow and perfusion of the

Abbreviations: COPD, chronic obstructive pulmonary disease; EECP, enhanced external counterpulsation; AT, anaerobic threshold; HR, heart rate; RR, respiratory rate; bpm, beats per minute; bpm*, breaths per minute; SBP, systolic blood pressure; DBP, diastolic blood pressure; VO₂, oxygen uptake; Mets, metabolic equivalent.

limbs, and strengthen the nutrition of slow and fast muscle fibers. Moreover, one study found that EECP therapy can induce the response of skeletal muscle cells, and increase the expression of IGF-1 and FGF-2 in skeletal muscle tissue, which is closely related to the metabolism of skeletal muscle cells and their ability to increase oxygenation.¹⁸

In patients with COPD, the present study showed that EECP therapy could also improve exercise endurance in this population. Although the pulmonary function was not determined in this group, a small sample study showed improvement of pulmonary function in patients with COPD and improvement of their 6-mins walking distance with EECP.²⁶ In theory, EECP can improve blood rheology, microcirculation, visceral tissue perfusion, blood flow to the lungs, and pulmonary ventilation/blood flow ratio, thus improving pulmonary oxygenation function.^{27,28}

Therefore, taken together, the results suggest that EECP could improve the cardiopulmonary functions of healthy adults and those with lower physical condition. In addition, even patients with a disease known to limit the physical condition severely may benefit from EECP. Considering that this intervention is non-invasive and is relatively inexpensive, it is worth popularization. The exact mechanisms by which EECP improves the cardiopulmonary functions still need to be determined, as well as the populations of individuals who may benefit the most from EECP.

This study has some limitations. The sample size was small, and the follow-up time was short. Therefore, the subgroup analyses must be considered as bases for future studies. Finally, stratified randomization was not used. The

results need to be confirmed using a large-scale multicenter clinical trial.

Conclusion

In conclusion, this pilot study suggests that EECP leads to a certain improvement effect on the exercise endurance of different adult populations, from healthy adults to those with COPD. Whether EECP can improve exercise tolerance of other diseases needs further study.

Ethics Approval and Informed Consent

This trial was conducted in accordance with the Declaration of Helsinki, and this preliminary randomized controlled trial was approved by the institutional review board of Jiangbin Hospital. Written informed consent was obtained from all the patients. The study was registered (ChiCTR1900021993).

Data Sharing Statement

The datasets used and/or analyzed during the current study are available from the corresponding author on reasonable request.

Funding

This study was funded by the Project for Guangxi Medical and Health Technologies (Grant Number: S2018116), Guangxi Health Commission Project (Grant Numbers: Z20190770, Z20190766), Science and Technology Foundation of Foshan City, China (Grant Number: 2017AG100061).

International Journal of Chronic Obstructive Pulmonary Disease

Dovepress

Publish your work in this journal

The International Journal of COPD is an international, peer-reviewed journal of therapeutics and pharmacology focusing on concise rapid reporting of clinical studies and reviews in COPD. Special focus is given to the pathophysiological processes underlying the disease, intervention programs, patient focused education, and self management

protocols. This journal is indexed on PubMed Central, MedLine and CAS. The manuscript management system is completely online and includes a very quick and fair peer-review system, which is all easy to use. Visit <http://www.dovepress.com/testimonials.php> to read real quotes from published authors.
